$\underline{3.2}$ Rolle's Thm.. and Mean Value Thm.
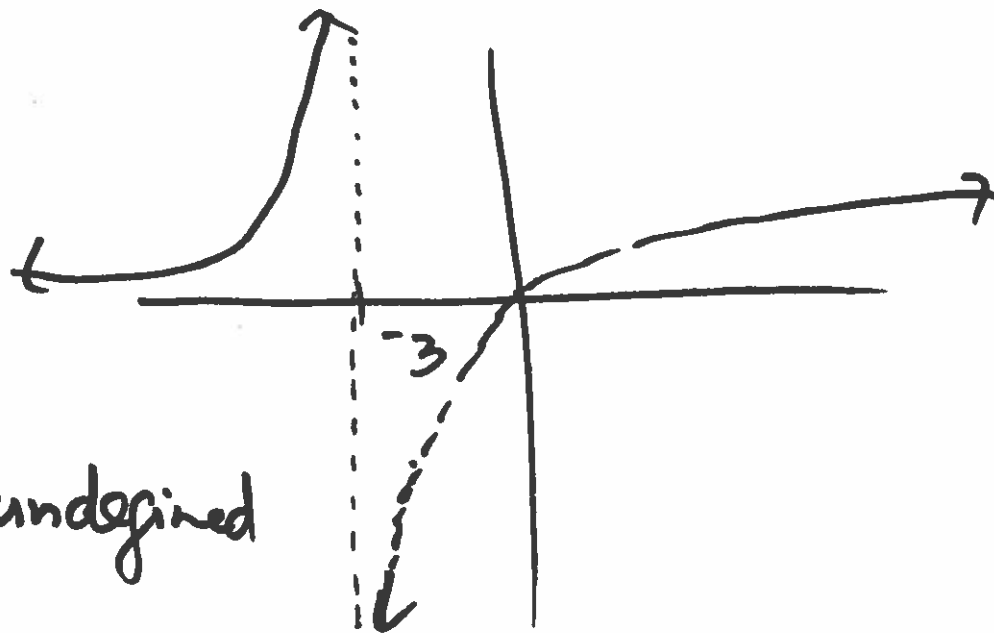

$$f(x) = \frac{x+1}{x+3} = \frac{N}{D}$$

$$y = (x+1)/(x+3)$$

If $x = -3$, $Y = \frac{-3+1}{-3+3} = $ undefined

$f(x)$ is discontinuous at $x = -3$

$$f'(x) = \frac{(x+3) \cdot D_x(x+1) - (x+1) \cdot D_x(x+3)}{(x+3)^2}$$

$$f'(x) = \frac{(x+3)(1) - (x+1)(1)}{(x+3)^2} = \frac{2}{(x+3)^2}$$

$$f'(0) = \frac{2}{(0+3)^2} = \frac{2}{9} \qquad f'(x) \text{ is defined at } x=0$$

$$f'(1) = \frac{2}{(1+3)^2} = \frac{1}{16} \qquad f'(x) \text{ is defined at } x=1$$

$$f'(-3) = \frac{2}{(-3+3)^2} = \frac{2}{0} = \text{undefined}$$

$$f'(x) \text{ is undefined at } x=-3$$

$$f'(x) = \frac{2}{(x+3)^2} \qquad \bigg| \qquad f(x) = \frac{x+1}{x+3}$$

$f'(x)$ is defined at $x=0$	$f(x)$ is differentiable at $x=0$
$f'(x)$ is defined at $x=1$	$f(x)$ is differentiable at $x=1$
$f'(x)$ is undefined at $x=-3$	$f(x)$ is not differentiable at $x=-3$

$$f(x) = 2x^3 \qquad\qquad [a, b] = [0, 6]$$

$f(x)$ is continuous on $(0, 6)$

$$f'(x) = 2 \cdot (3x^2) = 6x^2$$

$f'(x)$ is defined (or exists)
$$\text{on } (0, 6)$$

$$f(a) = f(0) = 2(0)^3 = 0$$
$$f(b) = f(6) = 2 \cdot (6)^3 = 72$$

$Y = 2x^3$

$$f(x) = x^2 - 3x + 2 \qquad [a, b] = [1, 2]$$

$f(x)$ is continuous on $(1, 2)$

$$f'(x) = 2x - 3$$

$f'(x)$ is defined (or exists)
on $(1, 2)$

$$f(a) = f(1) = (1)^2 - 3(1) + 2 = 0$$
$$f(b) = f(2) = (2)^2 - 3(2) + 2 = 0$$

Note: $f(a) = f(b)$

set $f'(x) = 0$
$$2x - 3 = 0$$
$$x = 1.5$$

Let $c = 1.5$

$$f'(c) = f'(1.5) = 2 \cdot (1.5) - (3) = 0$$

Rolle's Thm: If $f(x)$ is con't and $f'(x)$ exists on the interval (a, b) and $f(a) = f(b)$,

then there exists a number c between a and b such that $f'(c) = 0$.

$$f(x) = x^4 - 2x^2 \qquad [a, b] = [-2, 2]$$

Question: Can Rolle's Thm. be applied for $f(x)$? Yes

$f(x)$ is con't on $(-2, +2)$
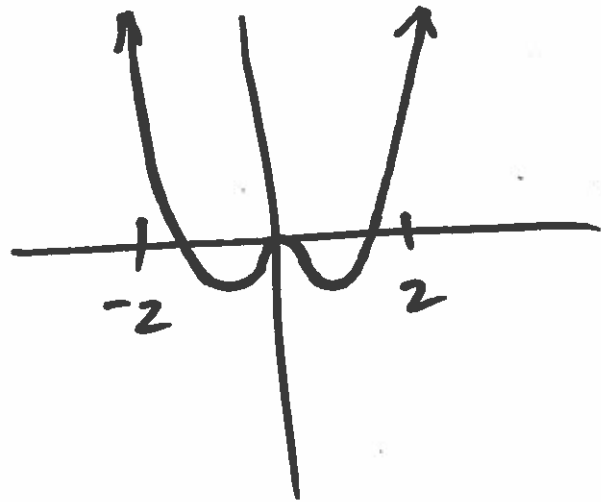

$$f'(x) = 4x^3 - 4x .$$

$f'(x)$ is defined (or exists)
on $(-2, 2)$

$$f(a) = f(-2) = (-2)^4 - 2(-2)^2 = 8$$
$$f(b) = f(2) = (2)^4 - 2(2)^2 = 8$$
$$f(a) = f(b)$$

So we can apply Rolle's Thm.

That means we can find a number $c \in (a, b)$ such that $f'(c) = 0$.

Finding c: set $f'(x) = 0$

$$4x^3 - 4x = 0$$

$$(4x)\cdot(x^2 - 1) = 0$$

$4x = 0$	$x^2 - 1 = 0$
$x = 0$	$x^2 = 1$
	$\sqrt{x^2} = \pm\sqrt{1}$
	$x = \pm 1$

Let $c = 0, -1, 1$

Note: $f'(0) = 0$
$f'(1) = 0$
$f'(-1) = 0$

$$f(x) = \frac{x^2 - 1}{x} \qquad [a, b] = [-1, 1]$$

Can we apply Rolle's Thm.? No

$f(x)$ is discon't at $x = 0$.

$f(x)$ is not con't on $(-1, 1)$

So we cannot apply Rolle's Thm.

$$f(x) = K \cdot \sqrt{x-4} \qquad [a, b] = [4, 10]$$

$f(x)$ is con't on $[a, b] = [4, 10]$

$$f(a) = f(4) = 4 \cdot \sqrt{4-4} = 0$$
$$f(b) = f(b) = 10 \cdot \sqrt{10-4} = 10\sqrt{6}$$
$$\text{so} \quad f(a) \neq f(b)$$

Therefore, Rolle's Thm. cannot be applied.

$f(x) = |x|$ $[a, b] = [-1, 1]$
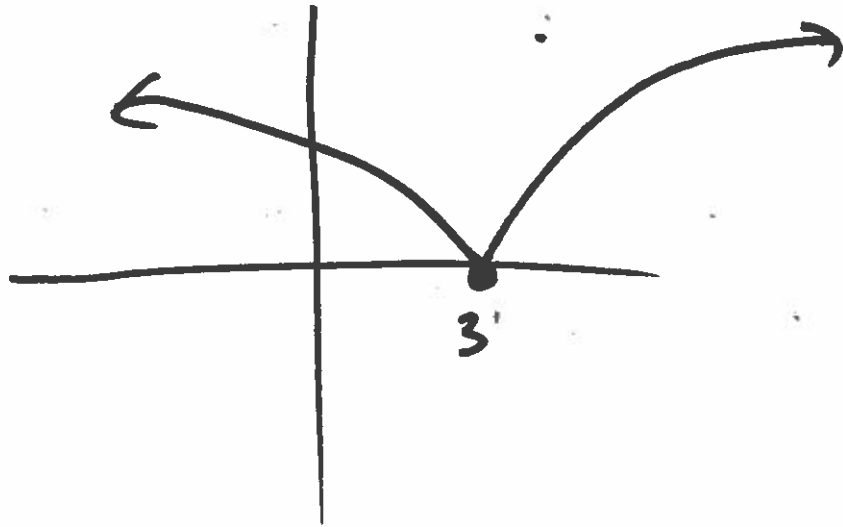

$f(x)$ is con't on $(-1, 1)$

"Sharp turn" point (0, 0) $\underset{x\ y}$

$f'(x)$ does not exist at "sharp turn" point.

$f'(x)$ does not exist at $x = 0$.

So we cannot apply Rolle's Thm.

Examples of "sharp turn" point:

$f'(x)$ does not exist at $x = 3$.
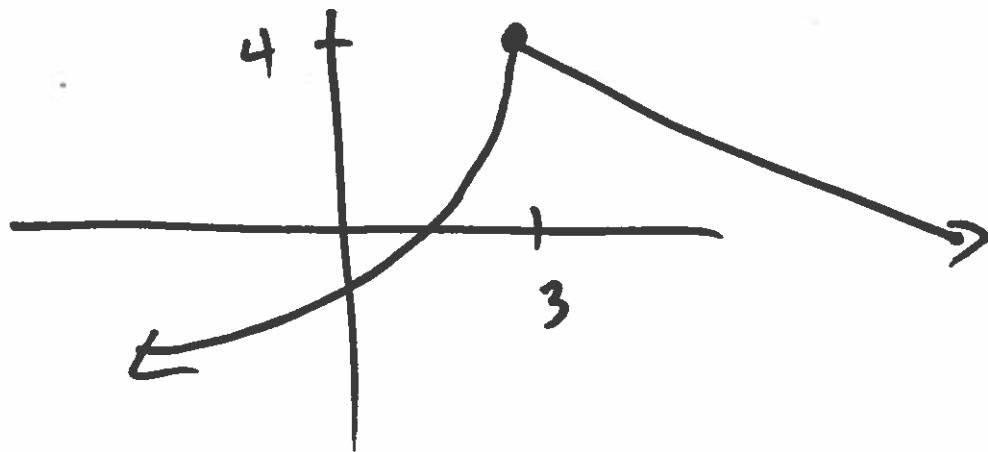

$f'(x)$ does not exist at $x = 3$.

Mean Value Thm.

$$f(x) = x^4 - 8x \qquad [a, b] = [0, 3]$$

$f(x)$ is con't on $(0, 3)$.
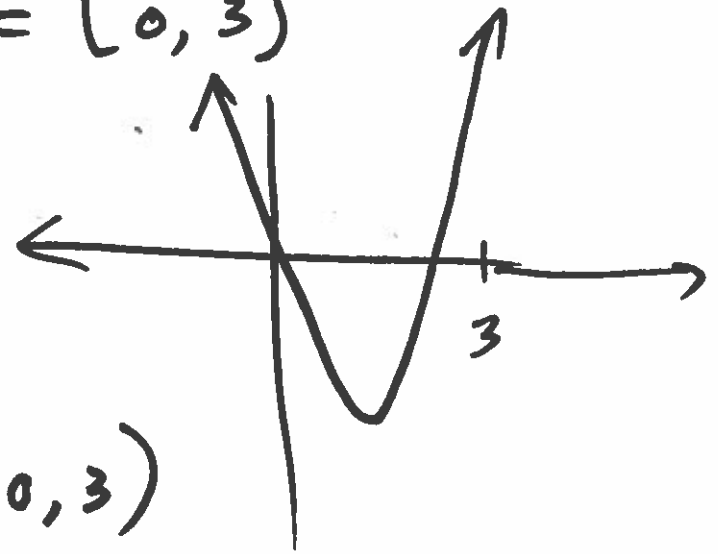

$$f'(x) = 4x^3 - 8$$

$f'(x)$ is defined (or exists) on $(0, 3)$

$$f(a) = f(0) = 0^4 - 8(0) = 0$$

$$f(b) = f(3) = 3^4 - 8 \cdot 3 = 57.$$

$$\frac{f(b) - f(a)}{b - a} = \frac{57 - 0}{3 - 0} = 57/3 = 19$$

set $f'(x) = \dfrac{f(b) - f(a)}{b - a}$

$$4x^3 - 8 = 57/3 = 19$$

$$4x^3 = 27$$

$$x^3 = 27/4$$

$$\sqrt[3]{x^3} = \sqrt[3]{27/4} = 1.889$$

$$\text{Let } c = \sqrt[3]{27/4} = 1.889$$

$$\text{Note}: f'(c) = 4(1.889)^3 - 8 = 19 = \frac{f(b)-f(a)}{b-a}$$

Mean Value Thm:

If $f(x)$ is con't and $f'(x)$ exists on (a, b).

Then, we can find a number $c \in (a, b)$ such that

$$f'(c) = \frac{f(b)-f(a)}{b-a}$$

Mean Value Thm:

$$f(x) = (x+2)^2 \qquad [a,b] = [0,2]$$

$f(x)$ is con't on $(0,2)$

$$f'(x) = 2 \cdot (x+2)^1 \cdot D_x (x+2)$$
$$= 2(x+2)(1)$$
$$f'(x) = 2x + 4$$

$f'(x)$ is defined (or exists) on $(0,2)$

So we can apply Mean Value Thm.
That means we can find a number $c \in (a,b)$
such that $f'(c) = \dfrac{f(b) - f(a)}{b-a}$
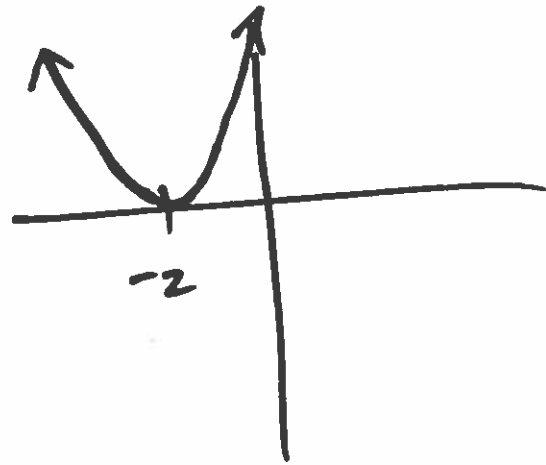

Finding c:
$$f(a) = f(0) = (0+2)^2 = 4$$
$$f(b) = f(2) = (2+2)^2 = 16$$
$$\frac{f(b) - f(a)}{b - a} = \frac{16 - 4}{2 - 0} = \frac{12}{2} = 6$$

set $f'(x) = 6$
$$2x + 4 = 6$$
$$2x = 2$$
$$x = 1$$

Let $c = 1$ Answer

Note: $f'(c) = f'(1) = 6 = \dfrac{f(b) - f(a)}{b - a}$
